⑦ Conclusions and Future Work

What is an Artificially Structured Boundary?

- An ASB is a configuration of electrodes and magnets that creates a static electromagnetic field that is short in range, affecting only the trajectories of particles that are very close to the material wall

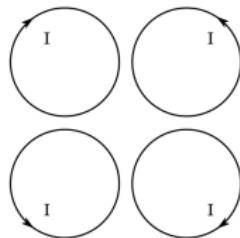

What is an Artificially Structured Boundary?

- An ASB is a configuration of electrodes and magnets that creates a static electromagnetic field that is short in range, affecting only the trajectories of particles that are very close to the material wall
- In the context of this presentation:
 - Spatially periodic arrangement of magnetic cusps
 - Cusps are electrostatically plugged to enhance confinement

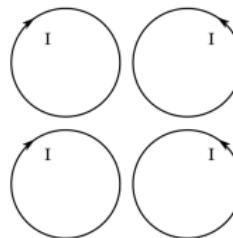

Examples:

- Examples:

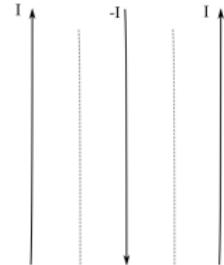

Checkerboard Dipole

Broken Line Cusp

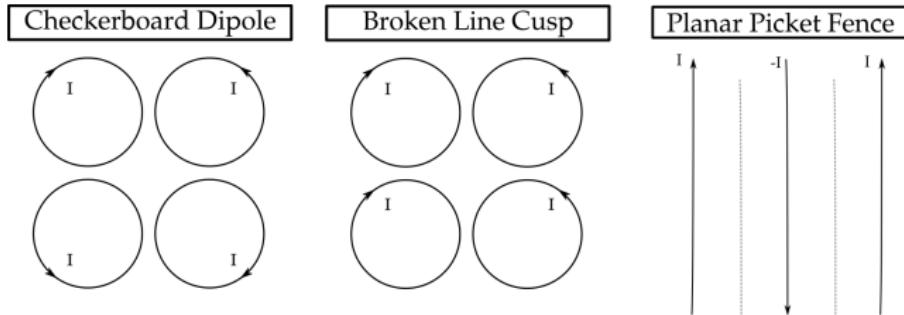

Planar Picket Fence

Examples:

- Examples:

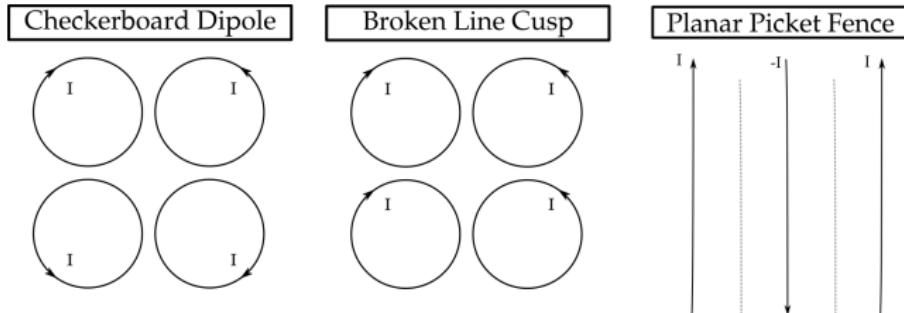

- Traps:

- Spherical Multipole Trap
- Cylindrical Multipole Trap
- Cylindrical Multi-cusp (Picket Fence)

Examples:

- Examples:

- Traps:

- Spherical Multipole Trap
- Cylindrical Multipole Trap
- Cylindrical Multi-cusp (Picket Fence)

- Old idea, new application

Motivations:

- Confinement volume is effectively free of external electromagnetic fields:
 - $B \approx 0 \implies$ Increase in three-body recombination rate by approximately an order of magnitude

Motivations:

- Confinement volume is effectively free of external electromagnetic fields:
 - $B \approx 0 \implies$ Increase in three-body recombination rate by approximately an order of magnitude
- Challenges for the production of cold \bar{H} in Penning traps:
 - Space-charge induced $\mathbf{E} \times \mathbf{B}$ drifts
 - Collisions between \bar{p} during mixing process

Outline

① Introduction

- What is an Artificially Structured Boundary?
- Motivations

② Methods

- Classical Trajectory Monte Carlo (CTMC) Simulations
- Particle-in-Cell (PIC) Simulations

③ CTMC: The Search for a Working Trap Configuration

④ Cylindrically Symmetric ASB Trap

⑤ PIC: Positron Plasma Confinement

⑥ PIC: Space-charge Confinement of Antiprotons

⑦ Conclusions and Future Work

Computational Challenges:

- Many possible geometries
- For dipole wall configurations, \mathbf{B} is expensive to compute (2-3 elliptic integrals/dipole/particle/time step)
- \Rightarrow Need a way to efficiently evaluate many geometries over a wide parameter space

Classical Trajectory Monte Carlo (CTMC) Simulation:

- A CTMC simulation suite was developed in C++ to:
 - Quickly simulate planar geometries
 - Gain baseline understanding of system requirements
 - Determine whether system should be further investigated via PIC
- Parallelized using OpenMP
- Boost C++ Libraries (ODEINT, Math, Random)
- Intel MKL fast Poisson solver used for calculation of electrostatic potential $\phi(\mathbf{r})$
- Normalized units used: $K_{0n} = m_n = q_n = S_n = 1$
 - Simulation results theoretically valid for any particle mass, charge state, initial kinetic energy, or spatial scale
 - Reality limits the applicability of the results (i.e., breakdown voltage, maximum current possible in wire, etc.)

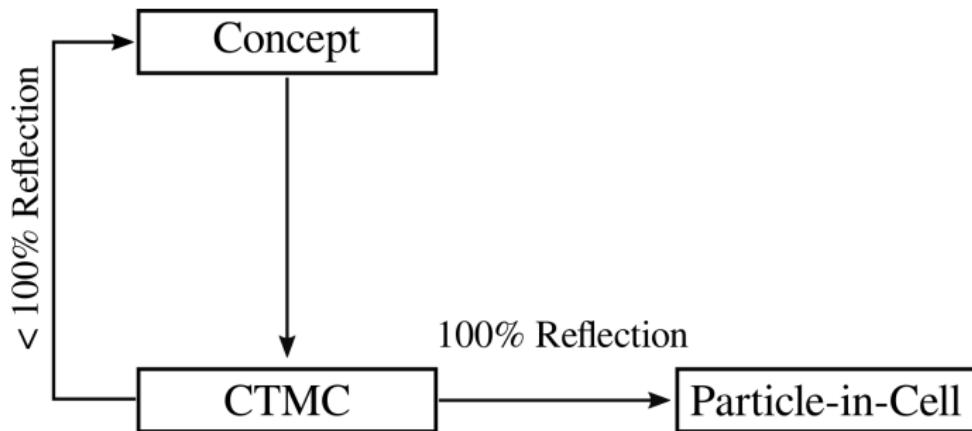

CTMC: Limitations

- Space-charge not included
- No collisional effects
- Poisson solver limited to 3D Cartesian or Spherical Geometry

Particle-in-Cell (PIC) Simulations: Warp

- Benefits:
 - Far more complete picture of plasma dynamics
- Challenges: All good things in life come at a cost...
 - **B** has high gradient near boundary \Rightarrow Fine grid
 - Plasma has sharp boundary near ASB \Rightarrow Fine grid
 - Fine grid + Large number of macro particles \Rightarrow Computation time is extensive
- Warp:
 - Multi-grid solvers
 - Static mesh refinement
 - Adaptive mesh refinement
 - Conductors easily implemented on mesh
 - Drift-Lorentz pusher

Method of Solution:

Outline

① Introduction

- Particle-in-Cell (PIC) Simulations

③ CTMC: The Search for a Working Trap Configuration

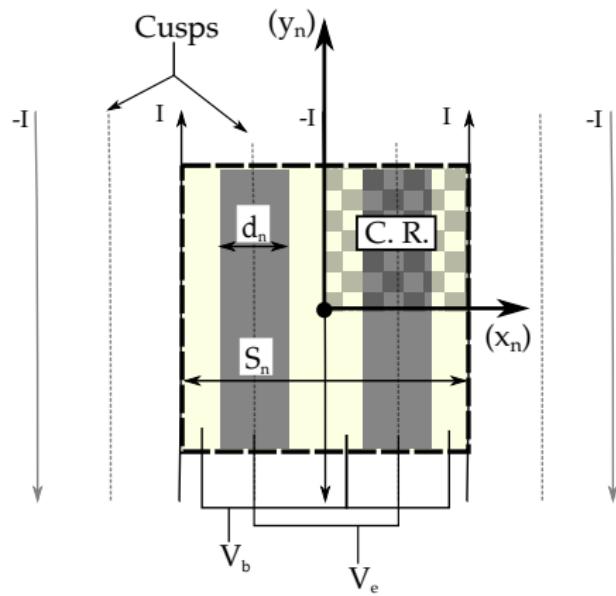

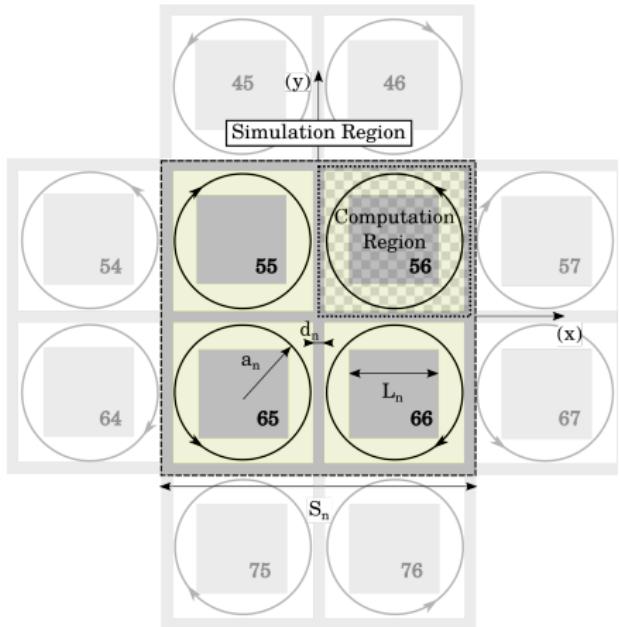

④ Cylindrically Symmetric ASB Trap

⑤ PIC: Positron Plasma Confinement

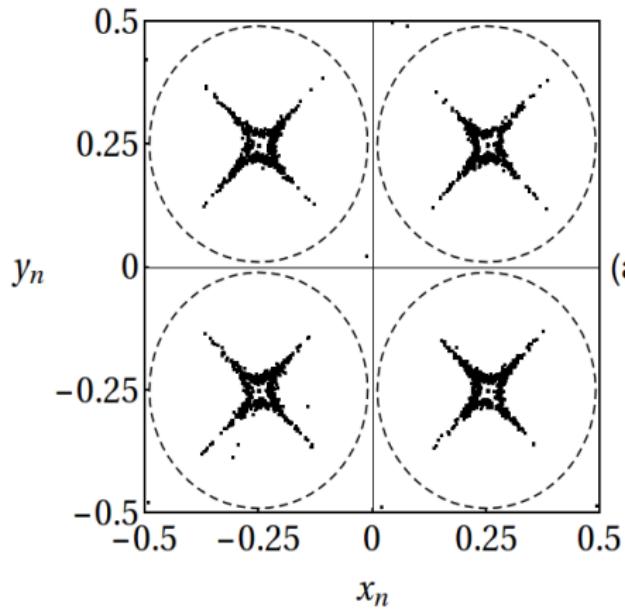

⑥ PIC: Space-charge Confinement of Antiprotons

⑦ Conclusions and Future Work

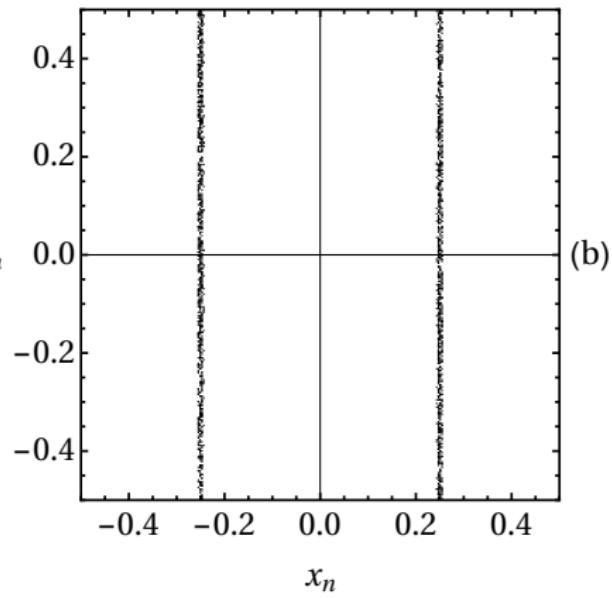

Systems studied via CTMC:

Spatial Distribution of Transmitted Particles:

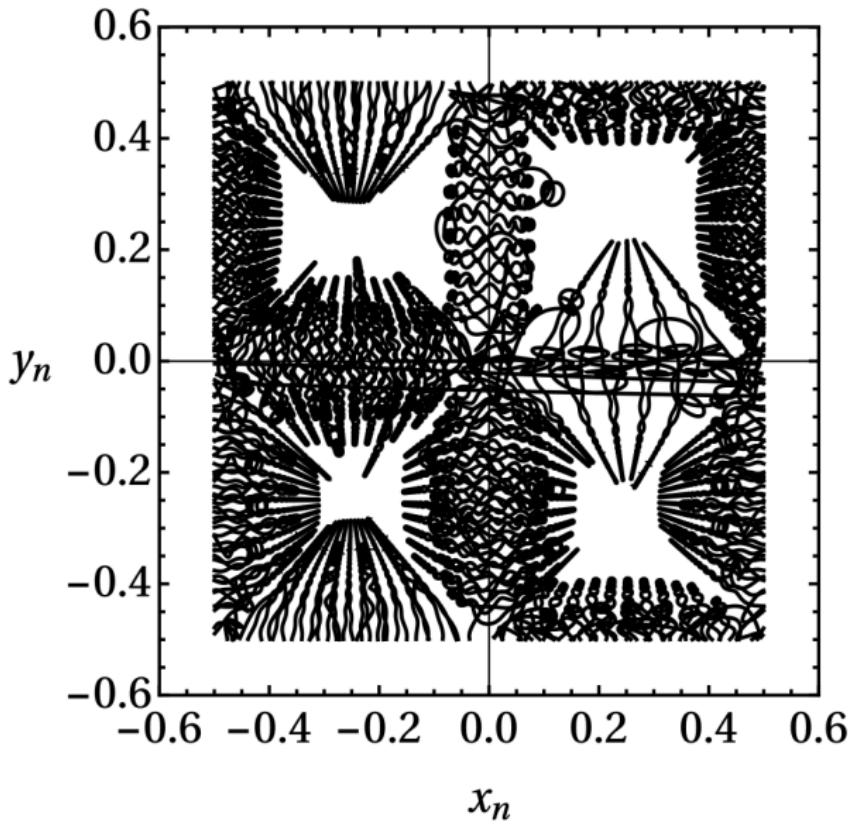

(a)

(b)

Checkerboard Dipole: Problematic Trajectories

Conclusions:

- 99% reflection possible for both geometries with $\mathbf{E} = 0$

Conclusions:

- 99% reflection possible for both geometries with $\mathbf{E} = 0$
- Dipole wall geometries:
 - Difficult to plug
 - Simulation time is extensive
 - Likely to be difficult to build

Conclusions:

- 99% reflection possible for both geometries with $\mathbf{E} = 0$
- Dipole wall geometries:
 - Difficult to plug
 - Simulation time is extensive
 - Likely to be difficult to build
- Picket fence:
 - Simple plugging electrode configuration
 - Easy generalization to a full trap design
 - $P_R = 100\%$ for a range of parameters
 - \Rightarrow Picket fence should be further examined with PIC

⑦ Conclusions and Future Work

Conclusions:

- CTMC:
 - Dipole wall configurations \implies Difficult to plug
 - Picket Fence configurations \implies Show promise

Conclusions:

- CTMC:
 - Dipole wall configurations \Rightarrow Difficult to plug
 - Picket Fence configurations \Rightarrow Show promise
- PIC: Single component positron plasma
 - Method of injection very important
 - A radial potential well is created
 - \Rightarrow It may be possible to confine \bar{p} in the potential well formed by the space-charge of the e^+ plasma

Conclusions:

- CTMC:
 - Dipole wall configurations \Rightarrow Difficult to plug
 - Picket Fence configurations \Rightarrow Show promise
- PIC: Single component positron plasma
 - Method of injection very important
 - A radial potential well is created
 - \Rightarrow It may be possible to confine \bar{p} in the potential well formed by the space-charge of the e^+ plasma
- PIC: Space-charge confinement of antiprotons
 - Injection method for the two species is very important
 - Stepped injection \Rightarrow Large amount of heating in both species
 - Simultaneous injection \Rightarrow Significant reduction in heating
 - If the injection of cryogenic e^+ and \bar{p} can be realized, space-charge based \bar{p} confinement may result in a larger number of cold \bar{H}

Future Work:

- Simulate the full ASB trap:
 - What is the depth of the axial space-charge potential well?
 - How should the ends of the trap be constructed?
 - How should the plasmas be injected so as to maintain cryogenic plasma temperatures?

Future Work:

- Simulate the full ASB trap:
 - What is the depth of the axial space-charge potential well?
 - How should the ends of the trap be constructed?
 - How should the plasmas be injected so as to maintain cryogenic plasma temperatures?
- What are the density and temperature limits of space-charge confined antiprotons?

Questions and Comments?

- Thank you for your attention

Properties:

Electrostatic Potential:

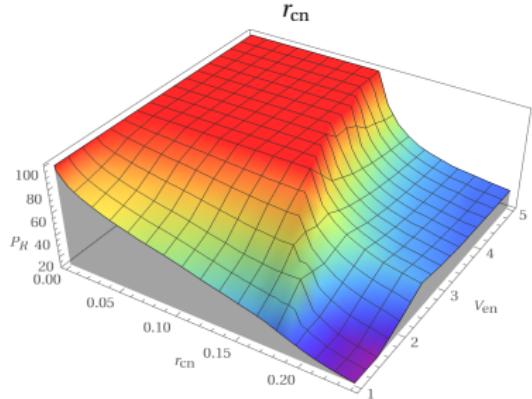

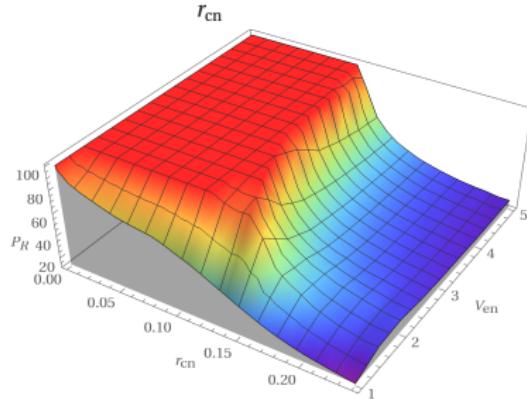

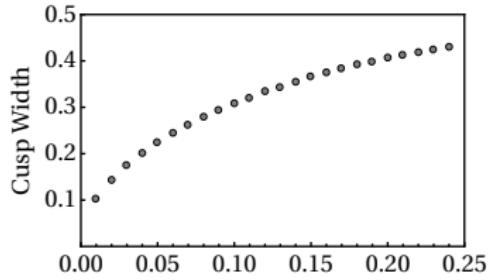

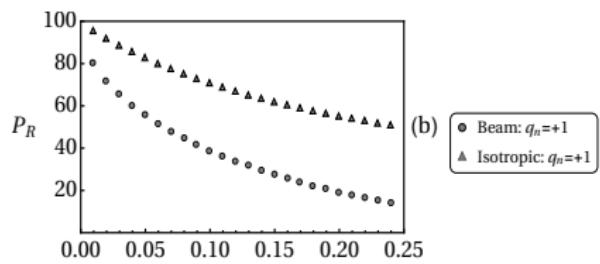

- Checkerboard: \Rightarrow Must be computed numerically
- Picket Fence: \Rightarrow Can be computed analytically

Magnetic Field:

- Checkerboard: \Rightarrow Two elliptic integrals per timestep, per current loop, per particle
- Picket Fence: \Rightarrow Simple functions:

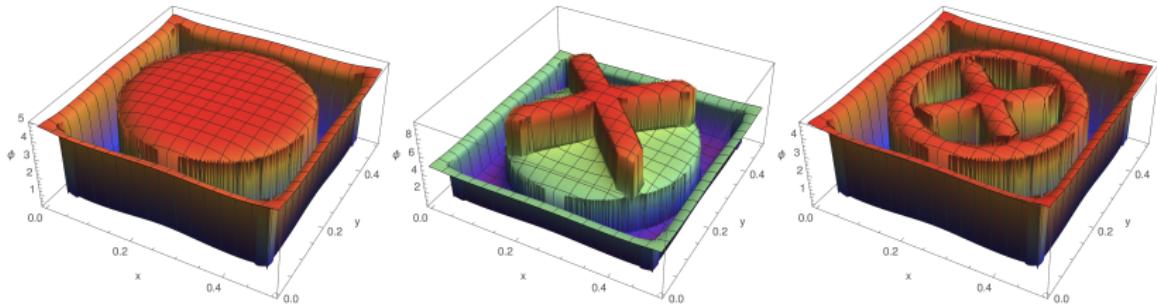

$$\begin{aligned} r_{cn} &= \frac{\sqrt{2mK_0}}{|q|B_m S}, & B_m &= 2\mu_0 I/S \\ \mathbf{B}_n &= \frac{\sqrt{2} \operatorname{sgn}(q)}{r_{cn}} (\beta_x(x_n, z_n) \hat{\mathbf{i}} + \beta_y(x_n, y_n) \hat{\mathbf{k}}) \\ \beta_x(x_n, z_n) &= -\frac{\cos(2\pi x_n) \sinh(2\pi z_n)}{\cos(4\pi x_n) - \cosh(4\pi z_n)} \\ \beta_y(x_n, z_n) &= \frac{\sin(2\pi x_n) \cosh(2\pi z_n)}{\cos(4\pi x_n) - \cosh(4\pi z_n)} \end{aligned} \tag{1}$$

Results: Picket Fence

Checkerboard Dipole:

- Electrostatic potentials must be computed numerically:

- Magnetic field is expensive to compute at each step:

$$\begin{aligned} B_{sn,r} &= \frac{\sqrt{2}}{\pi} \frac{\text{sgn}(q)}{r_{cn}} \eta_{1n}(r_n, z_n) [\kappa_{1n}(r_n, z_n) E(m_a) - K(m_a)], \\ B_{sn,z} &= \frac{\sqrt{2}}{\pi} \frac{\text{sgn}(q)}{r_{cn}} \eta_{2n}(r_n, z_n) [\kappa_{2n}(r_n, z_n) E(m_a) + K(m_a)], \end{aligned} \quad (2)$$

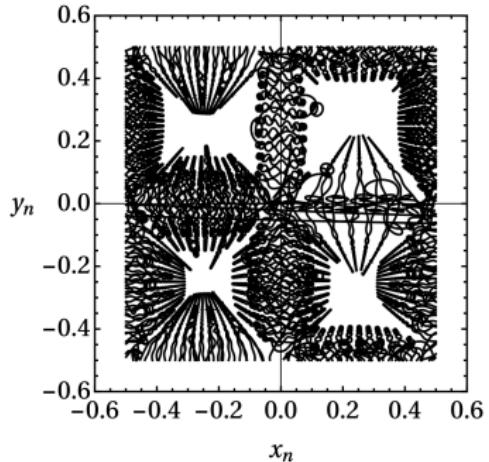

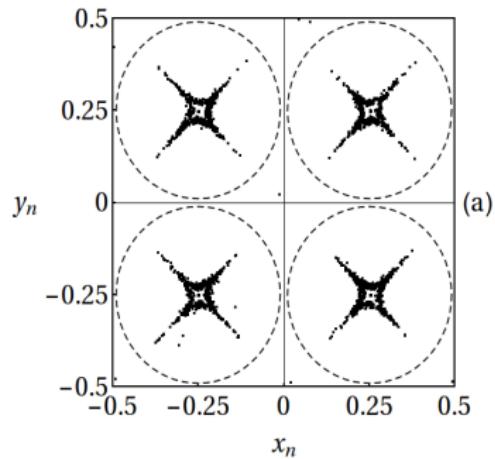

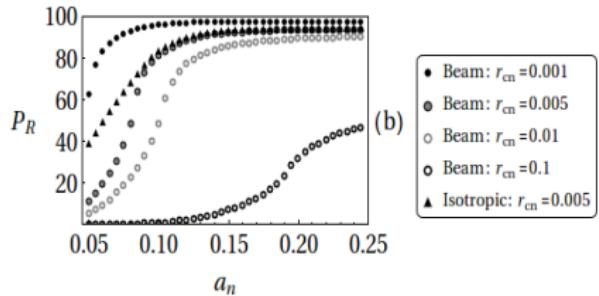

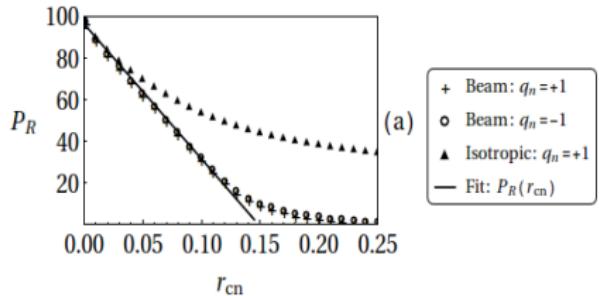

Picket Fence:

- Electrostatic potential can be calculated analytically by separation of variables
- Magnetic field is in terms of simple functions:

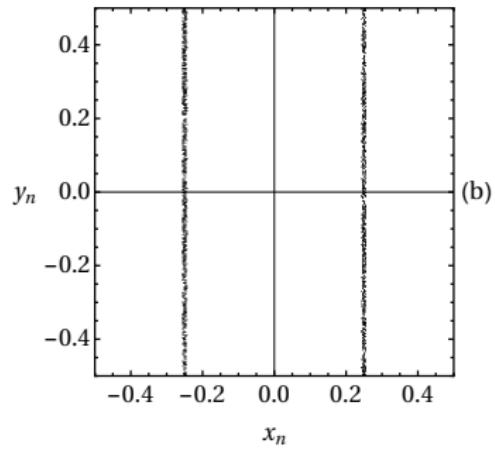

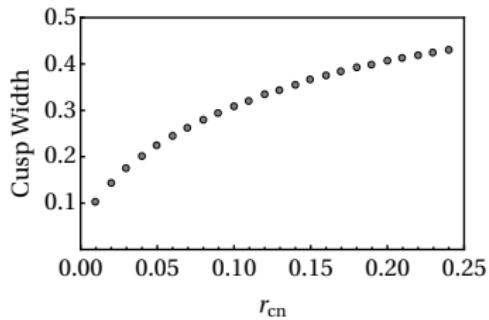

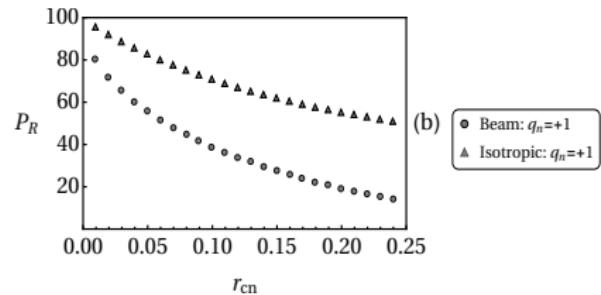

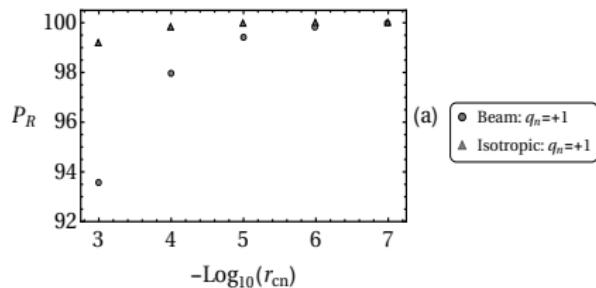

$$\mathbf{B}_n = \frac{\sqrt{2} \operatorname{sgn}(q)}{r_{cn}} (\beta_x(x_n, z_n) \hat{\mathbf{i}} + \beta_y(x_n, y_n) \hat{\mathbf{k}})$$
$$\beta_x(x_n, z_n) = -\frac{\cos(2\pi x_n) \sinh(2\pi z_n)}{\cos(4\pi x_n) - \cosh(4\pi z_n)}$$
$$\beta_y(x_n, z_n) = \frac{\sin(2\pi x_n) \cosh(2\pi z_n)}{\cos(4\pi x_n) - \cosh(4\pi z_n)} \quad (3)$$

- $r_{cn} = \frac{\sqrt{2mK_0}}{|q|B_m S}$
- $B_m = 2\mu_0 I/S$

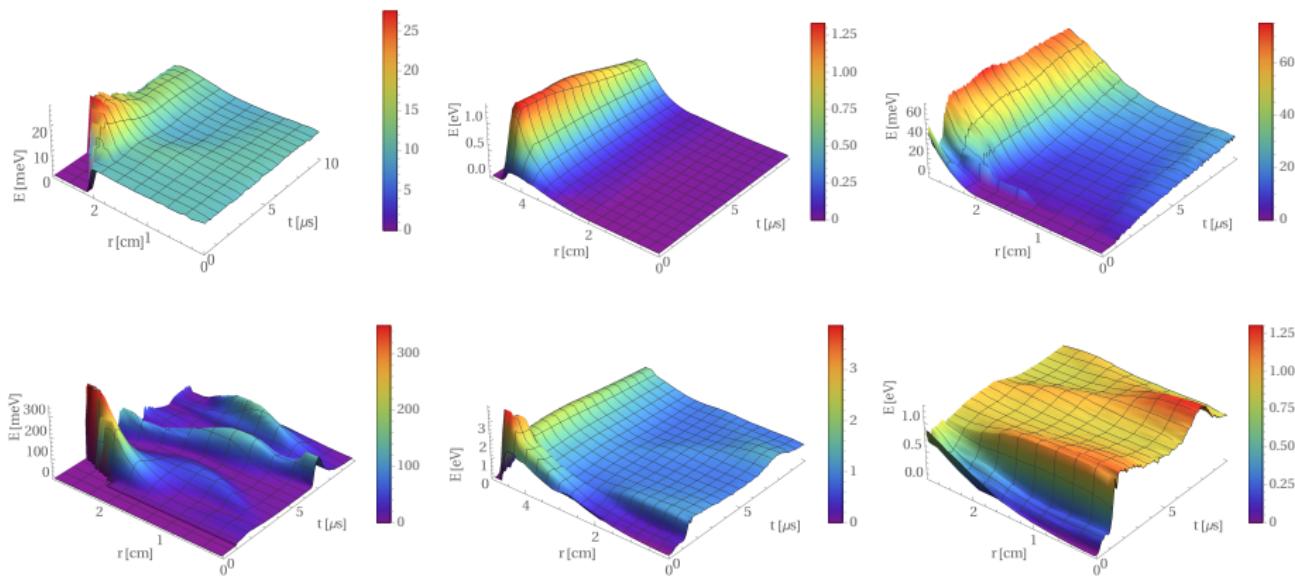

Results: Checkerboard Dipole
